

Proposal: I would create a Employee Entity for name, id, email. The Storage class is created to contain the list of Employees. I would also create a DAO Class for adding and retrieving employees. I would create a Controller which is very essential for REST API endpoints. I would also check that all the CRUD operations are working properly.

I would implement the complete CRUD operations:

GET – Retrieve all employees or retrieve an employee by ID.

POST – Add a new employee.

PUT – Update an existing employee's information.

DELETE – Remove an employee by ID.

```
package com.example.demo;
```

```
import org.springframework.web.bind.annotation.GetMapping;  
import org.springframework.web.bind.annotation.PostMapping;  
import org.springframework.web.bind.annotation.RequestBody;  
import org.springframework.web.bind.annotation.RestController;
```

```
@RestController
```

```
public class EmployeeController {
```

```
    private EmployeeManager employeeManager = new EmployeeManager();
```

```
    @GetMapping("/employees")
```

```
    public Employees getAllEmployees() {  
        return employeeManager.getEmployees();  
    }
```
